Vector Quantized Variational Autoencoders (VQ-VAEs)

## Gaussian VAEs for Faces 2014

We can sample faces from the VAE by sampling noise  $z$  from  $p_{\Phi}(z)$  and then sampling an image  $y$  from  $p_{\Phi}(y|z)$ .

[Alec Radford]

# VQ-VAE-2 Model

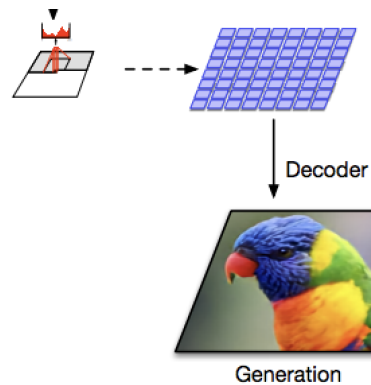

The probability of an image  $y$  is defined by the generator.

The generator is top-down and is similar to that of a progressive GAN.

## VQ-VAE-2 Model

We describe the case of just one layer.

A separate unit describes progressive VAEs which are inspired by an analogy with progressive GANs. Progressive VAEs provide a speculative method of multi-layer VQ-VAE training.

## The Single-Layer VQ-VAE

Let  $s$  denote the image (we are using  $y$  for an image coordinate).

We have an encoder network, such as a CNN, which produces a layer with a vector at each pixel position.

$$L[X, Y, I] = \text{Enc}_\Phi(s)$$

Intuitively we cluster the vectors  $L(x, y, I)$  using K-means clustering to produce cluster centers where  $C[k, I]$  is the cluster center vector of cluster  $k$ .

## VQ-VAE Model

We then replace each vector  $L[x, y, I]$  by the nearest cluster center to give  $\hat{L}[X, Y, I]$ .

$$z[x, y] = \operatorname{argmin}_k ||L[x, y, I] - C[k, I]||$$

$$\hat{L}[x, y, I] = C[z[x, y], I]$$

The “symbolic image”  $z[X, Y]$  is the latent variable.

## VQ-VAE Model

Finally we decode  $\hat{L}[X, Y, I]$  to get  $\hat{s}_{\Theta}(z)$ .

## Two-Phase Optimization

**Phase 1:** Fix the prior  $P_\Phi(z)$  at a simple (perhaps uniform) distribution and optimize the encoder  $P_\Psi(z|s)$  and the decoder  $P_\Theta(s|z)$ .

$$\text{for } \Theta^*, \Psi^* = \underset{\Theta, \Psi}{\operatorname{argmin}} E_{s \sim \text{Pop}, z \sim P_\Psi(z|s)} \ln \frac{P_\Psi(z|s)}{P_\Phi(z)} - \ln P_\Theta(s|z)$$

$$\text{we get } \Theta^* = \underset{\Theta}{\operatorname{argmin}} E_{s \sim \text{Pop}, z \sim P_{\Psi^*}(z|s)} [-\ln P_\Theta(s|z)]$$

**Phase 2:** Train the prior  $P_\Phi(z)$  holding the encoder and decoder fixed.

$$\Phi^* = \underset{\Phi}{\operatorname{argmin}} E_{s \sim \text{Pop}, z \sim P_{\Psi^*}(z|s)} [-\ln P_\Phi(z)]$$

Two phase training can be motivated by autonomy of the encoder. In principle the prior and the decoder can yield a perfect model for any encoder.

## Phase 1 Special Case

For a fixed uniform prior and a deterministic encoder we get

$$\begin{aligned}\Theta^*, \Psi^* &= \operatorname{argmin}_{\Theta, \Psi} E_{s \sim \text{Pop}, z \sim P_\Psi(z|s)} \left[ \ln \frac{P_\Psi(z|s)}{P_\Phi(z)} - \ln p_\Theta(s|z) \right] \\ &= \operatorname{argmin}_{\Theta, \Psi} E_{s \sim \text{Pop}, z \sim P_\Psi(z|s)} [-\ln p_\Theta(s|z)] \\ &= \operatorname{argmin}_{\Theta, \Psi} E_{s \sim \text{Pop}, z \sim P_\Psi(z|s)} (s - \hat{s}_\Theta(z_\Psi(s)))^2\end{aligned}$$

## Handling Discrete Latents

$$\Theta^*, \Psi^* = \operatorname{argmin}_{\Theta, \Psi} E_{s \sim P_{\text{op}}, z \sim P_{\Psi}(z|s)} (s - \hat{s}_{\Theta}(z_{\Psi}(s)))^2$$

$$z[x, y] = \operatorname{argmin}_k ||L[x, y, I] - C[k, I]||$$

$$\hat{L}[x, y, I] = C[z[x, y], I]$$

Since  $z[x, y]$  is discrete we have  $z[x, y].\text{grad} = 0$ .

## Handling Discrete Latents

$$\Theta^*, \Psi^* = \operatorname{argmin}_{\Theta, \Psi} E_{s \sim P_{\text{op}}, z \sim P_{\Psi}(z|s)} (s - \hat{s}_{\Theta}(z_{\Psi}(s)))^2$$

VQ-VAE uses “straight-through” gradients and “k-means” gradients.

$$L[x, y, I].\text{grad} = \hat{L}[x, y, I].\text{grad} + \beta(L[x, y, I] - C[z[x, y], I])$$

$$C[k, I].\text{grad} = \sum_{z[x, y]=k} \gamma(C[k, I] - L[x, y, I])$$

## One Layer VQ-VAE Training Phase 2

Finally we hold the encoder fixed and train the prior  $P_{\Phi}(z)$  to be an auto-regressive model of the symbolic image  $z[X, Y]$ .

## Quantitative Evaluation

The VQ-VAE2 paper reports a classification accuracy score (CAS) for class-conditional image generation.

We generate image-class pairs from the generative model trained on the ImageNet training data.

We then train an image classifier from the generated pairs and measure its accuracy on the ImageNet test set.

	Top-1 Accuracy	Top-5 Accuracy
BigGAN deep	42.65	65.92
VQ-VAE	54.83	77.59
VQ-VAE after reconstructing	58.74	80.98
Real data	73.09	91.47

# Image Compression

Figure 3: Reconstructions from a hierarchical VQ-VAE with three latent maps (top, middle, bottom). The rightmost image is the original. Each latent map adds extra detail to the reconstruction. These latent maps are approximately 3072x, 768x, 192x times smaller than the original image (respectively).

## Rate-Distortion Evaluation.

Rate-distortion metrics for image compression to discrete representations support unambiguous rate-distortion evaluation.

Rate-distortion metrics also allow one to explore the rate-distortion trade-off.

	Train NLL	Validation NLL	Train MSE	Validation MSE
Top prior	3.40	3.41	-	-
Bottom prior	3.45	3.45	-	-
VQ Decoder	-	-	0.0047	0.0050

Table 1: Train and validation negative log-likelihood (NLL) for top and bottom prior measured by encoding train and validation set resp., as well as Mean Squared Error for train and validation set. The small difference in both NLL and MSE suggests that neither the prior network nor the VQ-VAE overfit.

# DALL·E: A Text-Conditional Image dVAE

DALL·E is a text-conditional VQ-VAE model of images.

The Vector quantization is done independent of the text. However, the model of the probability distribution of the symbolic image  $z[x, y]$  is conditioned on text.

Ramesh et al. 2021
