### **RMSProp and Adam**

## **RMSProp and Adam**

RMSProp and Adam are “adaptive” SGD methods — they use different learning rates for different model parameters where the parameter-specific learning rate is computed from statistics of the data.

Adam is variant of RMSProp with momentum and “debiasing”.

## RMSProp

RMSProp was introduced in Hinton's class lecture slides.

RMSProp is based on a running average of  $\hat{g}[i]^2$  for each scalar model parameter  $i$ .

$$s_t[i] = \left(1 - \frac{1}{N_s}\right) s_{t-1}[i] + \frac{1}{N_s} \hat{g}_t[i]^2 \quad N_s \text{ typically } 100 \text{ or } 1000$$

$$\Phi_{t+1}[i] = \Phi_t[i] - \frac{\eta}{\sqrt{s_t[i]} + \epsilon} \hat{g}_t[i]$$

## RMSProp Analysis

For sufficiently small  $\epsilon$ , RMSProp makes the update independent of the scale of the gradient.

$$\Phi[i] -= \eta \frac{\hat{g}[i]}{\sqrt{s[i]}}$$

If the gradient  $\hat{g}_i$  is scaled up by a factor of  $\alpha$  we have that  $\sqrt{s[i]}$  is also scaled by  $\alpha$ .

This makes the learning rate  $\eta$  dimensionless.

## RMSProp Analysis

$$\Phi[i] -= \eta \frac{\hat{g}[i]}{\sqrt{s[i]}}$$

It is not completely clear why making the update invariant to gradient scaling is a good thing.

It would be nice to have an analysis directly tied to convergence rates.

## Adam — Adaptive Momentum

Adam combines momentum and RMSProp.

PyTorch RMSProp also supports momentum. However, it presumably uses the standard momentum learning rate parameter which couples the temperature to both the learning rate and the momentum parameter. Without an understanding of the coupling to temperature, hyper-parameter optimization is then difficult.

Adam uses a momentum parameter that is naturally decoupled from temperature.

Adam also uses “bias correction”.

## Bias Correction

Consider a standard moving average.

$$\tilde{x}_0 = 0$$

$$\tilde{x}_t = \left(1 - \frac{1}{N}\right) \tilde{x}_{t-1} + \left(\frac{1}{N}\right) x_t$$

For  $t < N$  the average  $\tilde{x}_t$  will be strongly biased toward zero.

## Bias Correction

The following running average maintains the invariant that  $\tilde{x}_t$  is exactly the average of  $x_1, \dots, x_t$ .

$$\begin{aligned}\tilde{x}_t &= \left(\frac{t-1}{t}\right) \tilde{x}_{t-1} + \left(\frac{1}{t}\right) x_t \\ &= \left(1 - \frac{1}{t}\right) \tilde{x}_{t-1} + \left(\frac{1}{t}\right) x_t\end{aligned}$$

We now have  $\tilde{x}_1 = x_1$  independent of any  $x_0$ .

But this fails to track a moving average for  $t \gg N$ .

## Bias Correction

The following avoids the initial bias toward zero while still tracking a moving average.

$$\tilde{x}_t = \left(1 - \frac{1}{\min(N, t)}\right) \tilde{x}_{t-1} + \left(\frac{1}{\min(N, t)}\right) x_t$$

The published version of Adam has a more obscure form of bias correction which yields essentially the same effect.

## Adam (simplified)

$$\tilde{g}_t[i] = \left(1 - \frac{1}{\min(t, N_g)}\right) \tilde{g}_{t-1}[i] + \frac{1}{\min(t, N_g)} \hat{g}_t[i]$$

$$s_t[i] = \left(1 - \frac{1}{\min(t, N_s)}\right) s_{t-1}[i] + \frac{1}{\min(t, N_s)} \hat{g}_t[i]^2$$

$$\Phi_{t+1}[i] = \Phi_t[i] - \frac{\eta}{\sqrt{s_t[i]} + \epsilon} \tilde{g}_t[i]$$

## Decoupling $\eta$ from $\epsilon$

$$\Phi_{t+1}[i] = \Phi_t - \frac{\eta}{\sqrt{s_t[i]} + \epsilon} \tilde{g}_t[i]$$

The optimal  $\epsilon$  is sometimes large. For large  $\epsilon$  it is useful to set  $\eta = \epsilon\eta_0$  in which case we get

$$\Phi_{t+1}[i] = \Phi_t - \frac{\eta_0}{1 + \frac{1}{\epsilon}\sqrt{s_t[i]}} \tilde{g}_t[i]$$

We then get standard SGD as  $\epsilon \rightarrow \infty$  holding  $\eta_0$  fixed.

## Making Adam Adapt to the Batch Size $B$

Adam already adapts to momentum by using an EMA of the gradient as momentum. Adapting to batch size requires some analysis.

$$\Phi[i] \leftarrow \eta \frac{\hat{g}[i]}{\sqrt{s[i]}}$$

Since we are taking a long moving average of  $\hat{g}[i]^2$  we can assume  $s[i] = E \hat{g}[i]^2$  and we have

$$\begin{aligned} s[i] &= E \hat{g}[i]^2 = \mu^2 + \sigma^2/B \\ \mu &= E \hat{g}[i] = E g[i] \\ \sigma^2 &= E(g[i] - \mu)^2 \end{aligned}$$

## Making Adam Adapt to the Batch Size $B$

$$\Phi[i] \leftarrow \eta \frac{\hat{g}[i]}{\sqrt{\mu^2 + \sigma^2/B}}$$

$$E \Delta\Phi = -\eta \frac{\mu}{\sqrt{\mu^2 + \sigma^2/B}}$$

For  $\mu^2 \gg \sigma^2/B$  we want  $\eta = B\eta_0$  as with vanilla SGD.

For  $\sigma^2/B \gg \mu^2$  we want  $\eta = \sqrt{B} \eta_0$ .

## Making Adam Independent of $B$

The previous analysis loses information. We could estimate  $g[i]^2$  more accurately by computing  $g[i]^2$  for each batch element rather than measuring  $\hat{g}[i]^2$  where  $\hat{g}[i]$  is already averaged over the batch.

This would require adding a batch index to the parameter gradients.
